## Part 1.1 — Convolutions from Scratch

I implemented 2D convolution two ways: a *4-loop* version and a faster *2-loop* version. Verified against `scipy.signal.convolve2d`.

```
# 4-loop conv (numpy only)
def conv2d_naive_4loops(img, kernel):
    img = img.astype(np.float32)
    k = np.array(kernel, np.float32)[::-1, ::-1] # flip
    H, W = img.shape; kh, kw = k.shape
    ph, pw = kh//2, kw//2
    p = np.pad(img, ((ph, ph), (pw, pw)), mode='constant')
    out = np.zeros((H, W), np.float32)
    for i in range(H):
        for j in range(W):
            acc = 0.0
            for u in range(kh):
                for v in range(kw):
                    acc += p[i+u, j+v] * k[u, v]
            out[i, j] = acc
    return out
```

```
# 2-loop conv (vectorized patch)
def conv2d_naive_2loops(img, kernel):
    img = img.astype(np.float32)
    k = np.array(kernel, np.float32)[::-1, ::-1]
    H, W = img.shape; kh, kw = k.shape
    ph, pw = kh//2, kw//2
    p = np.pad(img, ((ph, ph), (pw, pw)), mode='constant')
    out = np.zeros((H, W), np.float32)
    for i in range(H):
        for j in range(W):
            region = p[i:i+kh, j:j+kw]
```

```
out[i, j] = np.sum(region * k)
return out
```

Blurred Selfie

Partial Derivative Gx Selfie

Partial Derivative Gy Selfie

Gradient Magnitude Selfie

## Part 1.2 — Finite Difference Operator

Convolved *cameraman* with  $(D_x=[1,-1])$  and  $(D_y=[1;-1]^T)$ , then formed  $(\sqrt{G_x^2 + G_y^2})$  and thresholded it to make a binary edge map.

```
# Using convolve2d to compute finite differences
gx = convolve2d(img, np.array([[1,-1]]), mode='same', boundary='symm')
gy = convolve2d(img, np.array([[1],[-1]]), mode='same', boundary='symm')
mag = np.sqrt(gx**2 + gy**2)
edges = (mag > 0.1).astype(np.float32)
```

Gx.

Gy.

Magnitude.

Edges after thresholding.

## Part 1.3 — Derivative of Gaussian (DoG)

To reduce noise, I smooth with a Gaussian then differentiate (or use DoG kernels). Edges are much cleaner than raw finite differences.

```
# DoG filter example
g = cv2.getGaussianKernel(ksize=7, sigma=1.5)
gx = -np.arange(-3,4)/1.5**2 * g[:,0] # derivative part
dogx = convolve2d(img, gx[np.newaxis,:], mode='same', boundary='symm')
```

DoG  $\backslash(G_x)$ .

DoG  $\backslash(G_y)$ .

DoG magnitude.

## Part 2.1 — Image “Sharpening” (Unsharp Mask)

Unsharp masking:  $\text{sharpened} = \text{image} + \alpha \times (\text{image} - \text{blur})$ .

### Taj Mahal

Taj original.

Taj sharpened.

## Siblings

Siblings original.

Siblings sharpened ( $\alpha=1.5$ ,  $\sigma=1.0$ ).

## Blur → Sharpen Experiment

I picked a sharp image, blurred it, then tried to sharpen it again. Observations: The “recovered” image looks sharper and more detailed than the blurred version, but it cannot fully restore the lost high frequencies. Edges regain contrast but fine textures do not fully come back—showing unsharp masking enhances but does not recreate detail.

Original.

Blurred.

Unsharp "recovered".

---

## Part 2.2 — Hybrid Images

Low frequencies from one image + high frequencies from another.

Mom (low frequencies).

Dad (high frequencies).

Hybrid result.

---

## Part 2.4 — Multiresolution Blending

### Oraple (Vertical Seam)

Apple input.

Orange input.

Orapple blended result.

### Messi Hair + Pope Face (Irregular Mask)

Messi input.

Pope input.

Mask input.

Messi Hair + Pope Face blend.

### **Cotton Candy Dress (Irregular Mask)**

Cotton Candy texture.

Dress base image.

Dress mask input.

Cotton Candy Dress blended result.

I use **Laplacian stacks** for each input and a **Gaussian stack** of the mask. At every level  $i$ :  
$$\text{blend}_i = \text{mask}_i \cdot \text{LapA}_i + (1 - \text{mask}_i) \cdot \text{LapB}_i$$
The final result is the sum over all blended levels. This follows Burt & Adelson's multiresolution blending and smooths the transition across frequencies (fine detail to coarse structure).
